ULTRASOUND - CAROTID DOPPLER COMPLETE EVALUATION

PURPOSE: To evaluate the extracranial carotid and vertebral arterial system for atherosclerosis or stenosis

SCOPE: Applies to all US Doppler studies of the carotid arteries performed in Imaging Services / Radiology

ORDERABLE:
- US Doppler Carotid Bilateral / Complete

INDICATIONS:
- Carotid bruit
- Hemispheric neurological symptoms (e.g., stroke, TIA, amaurosis fugax)
- Non-hemispheric neurological symptoms (e.g., vertigo, ataxia, diplopia, drop attacks, sudden blurred vision, bilateral paresthesia)
- Unexplained neurological symptoms (e.g., syncope, headache, memory loss, and confusion)
- Trauma
- Pulsatile neck mass
- History of stenosis
- Prior endarterectomy
- Transplant or other major surgery evaluation
- Carotid stent evaluation

CONTRAINDICATIONS:
- Dizziness alone is not sufficient indication for this exam

EQUIPMENT:
Select a transducer that allows for appropriate penetration and resolution depending on body habitus.
- Linear transducer with a frequency range > 9 MHz

PATIENT PREPARATION:
- Introduce yourself to the patient
- Verify patient identity using patient name and DOB
- Explain test
- Obtain patient history including symptoms. Enter and store data page.
- Place patient in supine position

GENERAL GUIDELINES:
A complete examination includes evaluation of the bilateral common, extracranial internal carotid, and proximal external carotid arteries as well as the extracranial portions of bilateral vertebral arteries.
- The examination must be bilateral unless otherwise contraindicated
- A complete examination includes evaluation of the entire course of the accessible portions of each vessel
- Variations in technique must be documented (i.e., stents)
**TECHNIQUE:**
- Supine position with head tilted away from side of interest
- Equipment gain and display settings will be optimized while imaging vessels with respect to depth, dynamic range, and focal zones
  - Color-flow Doppler images with proper color scale to demonstrate areas of high flow and color aliasing
  - Spectral Doppler gains will be set to allow a spectral window and optimized to reduce artifact
  - An angle of 60 degrees or less will be used to measure velocities
  - Doppler angle should always be parallel to the vessel wall
- Perform evaluation in transverse followed by longitudinal, first right side then left.
  - Transverse images are taken perpendicular to the long axis of the vessel
  - Longitudinal images are taken along the long axis of the vessel
- In transverse plane, label External (E) and Internal (I) carotid arterials just distal to the bifurcation.
- Areas of suspected stenosis or obstruction will include spectral Doppler waveforms and velocity measurements recorded at and distal to the stenosis or obstruction
- Sites of interrogation will include spectral Doppler waveforms and velocity measurements from the proximal, mid, and distal sites
- Plaque should be assessed and characterized as smooth, irregular, homogenous, or heterogeneous.
  - Color and angle corrected spectral Doppler imaging may provide additional information including improved visualization of hypoechoic plaque
  - Transverse grayscale and color images of moderate to severe plaque should be documented
  - Cine any area of stenosis > 50% in longitudinal and transverse
- For ICA/CCA Peak Systolic Velocity ratio, use the highest PSV in the internal carotid artery and the PSV in the distal common carotid artery.
- Obtain bilateral brachial blood pressures
  - Image bilateral subclavian arteries if unable to attain bilateral pressures. Obtain the subclavian PSV to compare right to left.
  - If there is a > 20 cc/sec difference in the PSV or the BP from left to right, consider subclavian steal. Obtain waveforms of both the medial and lateral aspects of the subclavian artery.
- Special instructions for duplex of carotid stent:
  - Location of the carotid stent should be determined
    - Most typically stent is placed from CCA-to-ICA
    - Less commonly, may lie in the ICA only, CCA only, or CCA-to-ECA rarely

| **Included for Carotid Stent** | | | | | |
| Mid/distal CCA before stent (to establish inflow velocity): longitudinal | x | x | x | x |
| Proximal stent (in CCA/bulb): longitudinal | x | x | x | x |
| Mid stent in proximal ICA (usually site of original stenosis): longitudinal | x | x | x | x |
| Distal stent in Distal ICA: longitudinal | x | x | x | x |
| ICA immediately beyond stent: longitudinal | x | x | x | x |
| ECA: longitudinal | x | x | x | x |

*Perform on right side first, then left side
^Prefer dual/split screen image format
*Obtain if unable to take brachial pressure. If subclavian steal is suspected, obtain same images for lateral aspect of the subclavian artery as well.

PSV = peak systolic velocity
EDV = end diastolic velocity
CCA = common carotid artery
ICA = internal carotid artery
ECA = external carotid artery

---

[1] Grey Scale and Color Doppler columns indicate the presence of relevant images for each anatomy location.
**PROCESSING:**

- Review examination data
- Export all images to PACS
- Confirm data in Imorgon (if applicable)
- Note any cardiac devices (eg. aortic balloon pump; LVAD; external cardiac pacers; etc).
- Note any study limitations (in Tech Study Note or paper communication to radiologist, per workflow)

Consensus Panel Criteria (for use at PHHS)

- Normal
  - Primary: ICA PSV <125 cm/sec
  - Secondary: ICA EDV <40 cm/sec
- Stenosis <50%:
  - Primary: ICA PSV <125 cm/sec
  - Secondary: ICA/CCA PSV Ratio <2.0 ICA EDV <40 cm/sec
- Stenosis 50-69%:
  - Primary: ICA PSV 125-230 cm/sec
  - Secondary: ICA/CCA PSV Ratio 2.0-4.0 ICA EDV 40-100 cm/sec
- Stenosis 70%:
  - Primary: ICA PSV >230 cm/sec
  - Secondary: ICA/CCA PSV Ratio >4.0 ICA EDV >100 cm/sec
- Near Occlusion:
  - Primary: ICA PSV high, low, or undetectable
  - Secondary: ICA/CCA PSV Ratio variable
  - EDV variable
- Total Occlusion:
  - Primary: ICA PSV undetectable
  - Plaque Estimate: visible to no

In interpreting the findings from the internal carotid artery, the category of stenosis is determined by the category most represented from the data.

However, if PSV, EDV, or ICA/CCA ratio falls outside of the anticipated category, the category of stenosis is then determined by the preponderance of data. For example, if an ICA has a PSV of 133 cm/s (50-69%), but an EDV of 40 cm/s and ICA/CCA ratio of 1.7, then the stenosis category ought to be 1-49%.

Proper explanation and rationale for any discrepancy between the preliminary report and final report, as well as any deviation outside of the established criteria must be stated in the final report.
Carotid Artery Stenosis Grading After Stent

</tr>
</tbody>
</table>

*≥70% Recommend CTA
PSV, peak systolic velocity

References:

Plaque Characteristics

- Plaque descriptors: homogeneous, heterogeneous, and/or calcific
- Possible surface characteristics: smooth, irregular, or ulcerated

Flow Characteristics

- 1-49% Minimal or no spectral broadening
- 50-69% Increased spectral broadening
- 70-99% Marked spectral broadening
- Occlusion Absent flow, thumping signal may be noted at the origin of the occlusion
